1. (12 points) Consider the following Haskell function:

\[
f(0) = 1 \\
f(n) = f(n-1) - n + f(n-1) + 2
\]

(a) Complete the following table of values of \(f( )\):

<table>
<thead>
<tr>
<th>n</th>
<th>0</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
<th>5</th>
<th>6</th>
<th>...</th>
<th>10</th>
</tr>
</thead>
<tbody>
<tr>
<td>f(n)</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

(b) Show the recursion tree (i.e., draw a tree with one node for each function invocation, where the children of a node are the function calls that it makes) for evaluating \(f(3)\):

(c) Write a Java version of \(f( )\) which will produce the same results and have the same recursion tree:

(d) Estimate the big-O running time of your function in part (c)

(e) What is an easy way to make this function much more efficient, and what does the big-O running time become?
2. (6 points) What will be the output of the following C++ program?

```cpp
void printem(int n, int a, int &b)
{
    cout << n << ": " << a << " " << b << endl;
    a = 0;
    b = 0;
}

int main()
{
    int x, y;
    int *p, *q;
    x = 4; y = 2; printem(1, x, y);
    x += 3; y += 3; printem(2, x, y);
    p = new int;
    *p = 6; q = &x; printem(3, *p, *q);
    *q = *p; x += 3; printem(4, *p, *q);
    q = p; x += 3; printem(5, *p, *q);
    y = x; x = *p; printem(6, x, y);
}
```

(Recall that cout << a << b << endl; is the C++ equivalent of System.out.print(a); System.out.print(b); System.out.println();)

3. (2 points) In the above program, what statement needs to be added (and where) to properly deallocate the dynamically allocated memory?
4. (10 points) For these questions, use the following definition for a Node:

```java
class Node {
    int item;
    Node next;
}
```

(a) Consider the following Java method (in some class that has access to the definition of Node):

```java
void someFunc(Node head)
{
    Node p = head;
    Node q;
    while (p != null && p.next != null) {
        q = p.next;
        p.item = p.item + q.item;
        p.next = q.next;
        p = p.next;
    }
}
```

Show the result of executing `someFunc(head)` for the following list:

```
head -> 3 -> 8 -> 5 -> 7
```

(b) If `someFunc` were written in C++, what additional statement would need to be added (and where) to properly deallocate Nodes?

(c) Using the above definition of Node, write a Java method `countOddPairs(Node head)` which returns a count of the number of pairs of adjacent nodes in the list whose sum is odd. For example, calling `countOddPairs(head)` for the above list should return 2, since 3 + 8 and 8 + 5 are both odd, while 5 + 7 is even. Be sure to handle corner cases correctly.
5. (10 points) Here is Java code for one version of the insertion sort algorithm:

```java
public void insertionSort(int[] a, int n)
// sort a[0 .. n-1] into ascending order
{
    for (int k = 1; k < n; k++) {
        // insert a[k] into the sorted region a[0 .. k-1]
        for (int i = k; i > 0 && a[i - 1] > a[i]; i--) {
            int temp = a[i - 1];
            a[i - 1] = a[i];
            a[i] = temp;
        }
    }
}
```

(a) Trace the operation of insertion sort by showing the contents of `a[]` at the end of each pass through the outer loop; use the array `{5, 1, 2, 3, 4}`, where `n = 5`:

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>initial</td>
<td>5</td>
<td>1</td>
<td>2</td>
<td>3</td>
<td>4</td>
</tr>
<tr>
<td>1</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>2</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>3</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>4</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

(b) How many item comparisons `(a[i - 1] > a[i])` are performed in part (a)?

(c) How many swaps are performed in part (a)?

(d) What would be the numbers of comparisons and swaps for the array `{50, 1, 2, ..., 49}`, where `n = 50`?
6. (10 points) Here is Java code for the selection sort algorithm:

```java
public void selectionSort(int[] a, int n)
// sort a[0 .. n-1] into ascending order
{
  for (int k = n - 1; k > 0; k--)
  // find index of largest item in a[0 .. k]
    int largest = 0;
    for (int i = 1; i <= k; i++)
    // if (a[i] > a[largest]) largest = i;
    
    // move largest item to position k
    int temp = a[largest];
    a[largest] = a[k];
    a[k] = temp;
}
}
```

(a) Trace the operation of selection sort by showing the contents of `a[]` at the end of each pass through the outer loop; use the array `{5, 1, 2, 3, 4}`, where `n = 5`:

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>initial</td>
<td>5</td>
<td>1</td>
<td>2</td>
<td>3</td>
<td>4</td>
</tr>
<tr>
<td>4</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>3</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>2</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>1</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

(b) How many item comparisons `(a[i] > a[largest])` are performed in part (a)?

(c) How many swaps are performed in part (a)?

(d) What would be the numbers of comparisons and swaps for the array `{50, 1, 2, ..., 49}`, where `n = 50`?
7. (12 points) Consider the following Haskell code defining a datatype of binary trees, a binary search tree insertion function, and a preorder tree traversal:

```haskell
data Tree = Node(Int, Tree, Tree) | Null

bstInsert(x, Null) = Node(x, Null, Null)
bstInsert(x, Node(y, left, right)) =
  if x == y then Node(y, left, right)
  else if x < y then Node(y, bstInsert(x, left), right)
  else Node(y, left, bstInsert(x, right))

preOrder(Null) = [ ]
preOrder(Node(x, left, right)) = [x] ++ preOrder(left) ++ preOrder(right)

(Recall that ++ is the list concatenation operator: [1, 2] ++ [3, 4] yields [1, 2, 3, 4].)

(a) Write a Haskell function `find`, with type (Int, Tree) -> Bool, such that `find(x, t)` returns `true` if `x` is in the binary search tree `t`, and `false` otherwise:

```haskell
find(x, t) = ______________________________________
```

(b) Complete the following definition of a Haskell (actually HasCl) function `bstInsertAll`, with type ([Int], Tree) -> Tree, such that `bstInsertAll(xs, t)` is the result of inserting all of the values from the list `xs` into the binary search tree `t`:

```haskell
bstInsertAll([ ], t) = __________________________

bstInsertAll([x : xs], t) = bstInsert(x, __________________________)
```

(c) Give a Haskell definition for an inorder traversal function:

```haskell
```
8. (8 points) What is the output when the main method of the Mystery class is executed?

```java
public interface LazyList {
    public int next();
}

public class Ints implements LazyList {
    private int n;
    public Ints(int n) {
        this.n = n;
    }
    public int next() {
        n++;
        return n;
    }
}

public class Filter implements LazyList {
    private LazyList list;
    private int p;
    public Filter(LazyList list, int p) {
        this.list = list;
        this.p = p;
    }
    public int next() {
        int n = list.next();
        while (n % p == 0) {
            n = list.next();
        }
        return n;
    }
}

public class Mystery implements LazyList {
    private LazyList list;
    public Mystery() {
        this.list = new Ints(1);
    }
    public int next() {
        int p = list.next();
        list = new Filter(list, p);
        return p;
    }
    private static void test(LazyList x) {
        for (int i = 0; i < 5; i++) {
            System.out.print(x.next() + " ");
        }
        System.out.println();
    }
    public static void main(String[] args) {
        System.out.println("Ints");
        test(new Ints(1));
        System.out.println("Filter");
        test(new Filter(new Ints(1), 2));
        System.out.println("Mystery");
        test(new Mystery());
    }
}
```
